(54) Title: DIAGNOSTIC SYSTEM FOR MONITORING COOKING PROFILES

(57) Abstract

The diagnostic system of the present invention monitors and accumulates the thermal signatures or characteristics during at least one operational mode of the cooking appliance. These thermal signatures or characteristics are collected — through the same temperature sensor used to regulate the temperature of the cooking appliance — and then stored in, for example, a look-up table. Advantageously, this may be accomplished without the need of special sensors or interface boards. The thermal signatures or characteristics may include first order or higher order temperature gradients, as well as temperature profiles. The stored thermal signatures provide a baseline from which the diagnostic system can detect and identify whether the cooking appliance is working under normal operating conditions. In an alternative embodiment, the diagnostic system monitors and accumulates the cooking profiles for either a single food product or a plurality of food products. The current cooking profile is

graphically displayed and compared against the master cooking profile to flag food products that are improperly cooked or not cooked to the proper degree of doneness. Such monitoring and analysis substantially eliminates any possible health risks. Also, such master cooking

DIAGNOSTIC SYSTEM FOR MONITORING COOKING PROFILES

CROSS-REFERENCE TO RELATED APPLICATION

5 This is a continuation-in-part of U.S. Patent Application No. 08/549,098, filed October 27, 1995, entitled "Diagnostic System For A Cooking Appliance," which is incorporated herein by reference.

10 TECHNICAL FIELD

The present invention relates generally to a diagnostic system, and more particularly, to a diagnostic system for detecting abnormal cooking conditions or malfunctions in a cooking appliance, as well as for monitoring the cooking parameters of the cooking appliance.

BACKGROUND OF THE INVENTION

Microprocessor based controllers have been developed in recent years to assist in the preparation of properly cooked foods. Typically, such controllers, among other things, regulate the temperature within the cooking appliance to insure that the food is cooked or baked to the proper degree of doneness. Advantageously, such controllers may use intelligent sensing and diagnostics built into the cooking appliance and coupled through an interface board to detect and identify various types of failures. See, for example, U.S. Patent No. 5,043,860 and applicants' copending application U.S. Serial No. 08/501211, entitled "Multiprobe Intelligent Diagnostic System For Food-Processing Apparatus" which are commonly assigned and incorporated herein by reference.

35 While these so-called "smart interface" boards perform excellently, they generally require the use of multiple sensors. Accordingly, although these "smart interface" boards are well-suited for modern cooking appliances, they

-2-

are ill-suited for the hundreds of thousands of cooking appliances manufactured over the last twenty years that use single temperature sensors. While retrofitting these older cooking appliances with additional sensors and interface boards would solve the problem, the associated cost makes it prohibitively expensive to do so.

Accordingly, what is needed is a simple and low cost diagnostic system to diagnose that certain physical characteristics of the cooking appliance are not working properly - all without the need of special sensors and interface boards.

Also, any variation in one or more of the cooking parameters alters the quality of the cooked food product, which may pose health risks. To ensure that the food product is cooked properly, it would be further desirable to provide a method and diagnostic system for monitoring the cooking operation of the appliance which readily detects such variations in an objective manner.

SUMMARY OF THE INVENTION

The diagnostic system of the present invention monitors and accumulates the thermal signatures, profiles or characteristics during different operational modes of the cooking appliance. These thermal signatures, profiles or characteristics are collected - through the same temperature sensor used to regulate the temperature of the cooking appliance - and then stored in, for example, a look-up table. Advantageously, this may be accomplished without the need of special sensors or interface boards. The thermal signatures or characteristics may include first order or higher order temperature gradients, as well as temperature profiles, collected, for example, when the temperature of the cooking appliance is raised to a desired

-3-

cooking temperature. The stored thermal characteristics or signatures provide a baseline from which the diagnostic system can detect and identify whether the cooking appliance is working under normal operating conditions.

5

In one exemplary embodiment, the diagnostic system of the present invention compares the measured temperature gradients collected during an operational mode of the cooking appliance with predetermined or learned minimum and/or maximum value(s) of the temperature gradient. Such minimum and maximum values may be based on any particular set of cooking conditions, including the type and model number of the cooking appliance. Moreover, so-called "fuzzy logic" may be used to identify abnormal operating conditions or malfunctions. Regardless of the logic used, if abnormal operating conditions are detected, an appropriate signal can be displayed to the user or transmitted to a remote monitoring station to effect maintenance.

10
15
20

In another embodiment of the present invention, the diagnostic system of the present invention alternatively monitors and accumulates the cooking profiles for either a single food product or a plurality of food products. The current cooking profile is graphically displayed and compared against the master cooking profile to flag food products that are improperly cooked or not cooked to the proper degree of doneness. Such monitoring and analysis substantially eliminates any possible health risks. Also, such master cooking profiles also provide a baseline for diagnosing between normal and faulty cooking conditions.

30
35
In this latter embodiment, a cooking bar envelope representing the lower and upper deviation limits from the master cooking profile can also be superimposed with the

-4-

current cooking profile. In this manner, out-of-tolerance cooking conditions are more readily discernable to indicate faulty conditions as well as unacceptable cooked food products.

5

BRIEF DESCRIPTION OF THE DRAWING

The features and advantages of the present invention will become more readily apparent from the following detailed description of the invention in which like elements are labeled similarly and in which:

Fig. 1 is a block diagram of a cooking appliance utilizing the diagnostic system of the present invention;

Fig. 2 is a plot of temperature versus time for a typical cooking appliance;

Fig. 3 is a plot of the temperature characteristics or profiles of a cooking appliance;

Fig. 4 is an illustrative cooking profile with temperature as the cooking parameter;

Fig. 5 is a block diagram of a cooking appliance utilizing another embodiment of the diagnostic system of the present invention;

Fig. 6 is an illustrative display of the current cooking profile superimposed with the master cooking profile; and

Fig. 7 is an illustrative display of the cooking bar envelope superimposed with the current cooking profile.

DETAILED DESCRIPTION

Without any loss of generality or applicability for the principles of the present invention, in some embodiments the description is directed to cooking appliances, such as fryers. It should be understood, however, that the term cooking appliance shall be understood to include deep fryers, refractory ovens, baking

-5-

ovens, combination ovens, infrared ovens, rotisseries, and in general temperature control units which, for example, may be cooling units.

5 A diagnostic system for use with a cooking appliance 105 having a heating element 110 and thermal probe 115 is shown in Fig. 1. Thermal probe 115 may be located in proximity to heating element 110 so as to measure the temperature at that location, and hence approximate the
10 temperature of heating element 110, such as in an oven. Depending on the type of the cooking appliance, thermal probe 115 alternatively may be located in a location for submersion into the cooking medium, such as cooking oil. In either case, thermal probe 115 measures the temperature
15 of the cooking medium.

A system controller 120 of cooking appliance 105 runs the diagnostic system as well as manages a number of other diagnostic and control functions. Preferably, system
20 controller 120 uses a microprocessor 125 having a random access memory (RAM) 130 and hardware logic 135. Under program control, microprocessor 125 regulates various operations of the cooking appliance, such as, for example, the cooking time and cooking temperature for either a
25 single food product or a plurality of food products. That is, the cooking appliance can be programmed to operate with cooking parameters tailored for a specific product. See, for example, U.S. Patent No. 4,920,948, which is incorporated herein by reference. Those skilled in the art
30 will readily note that such cooking parameters may be either preprogrammed at the factory or entered by a user at the time of cooking, such as through a keypad 140. Thermal probe 115 is connected to an analog-to-digital converter 145 which supplies digital signals to microprocessor 125 indicative of the temperature of heating element 110 or
35

-6-

alternatively the cooking medium. Thermal probe 115 may be
resistance temperature detectors, thermistors,
thermocouples and the like. The choice of the thermal
probe depends on the range of the temperatures to be
5 measured. Microprocessor 125 processes the digital
temperature signals using a program and data stored in a
read-only-memory 150.

It should be understood that microprocessor 125
10 includes such hardware as a central processing unit,
program and random access memories, timing and control
circuitry, input/output (I/O) interface devices and other
digital subsystems necessary to the operation of the
central processing unit. Those skilled in the art will
15 readily note that the diagnostic system of the present
invention may be completely implemented using analog
circuitry. The diagnostic system operates in accordance
with a program whose methodology of operation is set forth
below herein. This diagnostic program can be stored in
20 conventional random-access-memory 150 or in a pre-
programmed chip, such as EPROM or EEPROM. It is
contemplated, however, that the diagnostic program may be
disabled by depressing a key on keypad 140, if so desired.

25 During normal operation, system controller 120 of
cooking appliance 105 regulates the percentage of time
power is applied to heating element 110 in accordance with
the cooking parameters selected by the user. For example,
the heating element or heating elements may be pulsed with
30 either a fixed or variable duty cycle (proportional control
heating), may be fully turned on, or operated in an on/off
manner similar to a thermostat, depending on the heating
mode of the cooking appliance. Such techniques minimize
overshoot and recovery time. The particular technique
selected depends, for example, on how rapidly the selected

-7-

temperature needs to be reached and the amount of overshoot that is acceptable. The particular technique used to regulate the temperature, however, is not critical to the operation of the present invention inasmuch as the 5 invention may be used with any or all of these techniques.

Preferably, electronics 155 for thermal probe 115 may reside in system controller 120. System controller 120 may have a light emitting diode or vacuum fluorescent device 10 display. Upon receiving the temperature data collected by thermal probe 115 during a cycle(s) or mode(s) of operation of the cooking appliance, system controller 120 automatically runs the diagnostic program in accordance with the principles of the invention. The diagnostic 15 system of the present invention monitors and accumulates the thermal signatures or characteristics during at least one operational mode of the cooking appliance. These thermal signatures or characteristics are collected through thermal probe 115 - the same probe used to regulate the 20 temperature of the cooking appliance - and then are stored in random-access-memory 130 in the form of, for example, a look-up table. Advantageously, this is accomplished without the need of special sensors or interface boards. The thermal signatures or characteristics include first 25 order or higher order temperature gradients or temperature profiles collected, for example, when the temperature of the cooking appliance is raised to a desired cooking temperature. For example, in a fryer, the thermal signatures or characteristics may be collected during "cold 30 start," "melt cycle," "cooking," and/or "idle." Preferably, it is done so after the melt cycle and during idle when the cooking appliance is establishing its normal operating temperature. During that time the temperature gradient is substantially constant or fixed. The stored 35 thermal signatures provide a baseline from which the

-8-

diagnostic system can detect and identify whether the cooking appliance is working under normal operating conditions.

5 Referring to Fig. 2, in one exemplary embodiment, the diagnostic system of the present invention monitors the temperature from cold start temperature 160 up to an operating temperature 165 of the cooking appliance. Then, the diagnostic system calculates the thermal gradient
10 during the time heating element 110 is fully on by determining the differential change in temperature, $\Delta T = T_2 - T_1$, during the time $\Delta t = t_2 - t_1$. Inasmuch as the microprocessor regulates the amount and the manner in which power is applied to the heating element, it is relatively
15 straightforward to measure the temperature at different portions of the temperature profile of the cooking appliance, regardless of the manner in which the heating element is controlled.

20 Those skilled in the art will also readily note that the time, Δt , may be tracked through the use of software counters. The quantity $\Delta T / \Delta t$, however, is the first order thermal gradient. The calculated temperature gradient is then compared with predetermined or learned minimum and/or
25 maximum values of the temperature gradient. Such minimum and maximum values are usually determined empirically from a cooking appliance known to function properly and may be based on any particular set of cooking conditions, including the type and model number of the cooking
30 appliance.

35 Alternatively, in another embodiment, the temperature profile(s) - that is, its shape - or any portion thereof is measured and stored. The temperature profile varies according to the particular malfunction. Once the

-9-

temperature profiles are empirically determined for known malfunctions, subsequent temperature profiles may be matched to those associated with particular malfunctions for identification.

5

Referring to Fig. 3, thermal profiles 310 and 320 for a cooking appliance that is operating properly and improperly, respectively, are depicted. Thermal profile 310 may be saved and stored in the memory of microprocessor 125 as training data. Accumulation of the thermal profiles for different malfunctions, such as faulty heating elements and electronics, provides a baseline for diagnostic purposes. Such training data may be used to teach the diagnostic system to diagnose between normal and abnormal 10 operating conditions.

Factors that may affect the measured temperature gradient or temperature profile include: gas pressure and available BTU energy; electrical voltage; amount and type 20 of cooking medium in the cooking appliance; and/or malfunctioning heating elements or heat exchangers. Any improper operation in the heating manifest itself as a variation in the temperature gradient or temperature profile outside the normal range of operations. It is contemplated that in certain instances, higher order 25 temperature gradients may be used where the desired temperature profile or a portion thereof is not substantially linear, such as during proportional control heating. If the diagnostic program determines that the measured temperature characteristics, such as the temperature gradient, are outside the normal operating 30 range, an appropriate signal - either audible or visual - can be displayed to the user or transmitted, including by wireless means, to a remote monitoring station to effect maintenance. For example, the communication system of U.S. 35

-10-

Patent No. 4,812,963, which is incorporated herein by reference, may be used to provide real-time diagnostic information to a remote station. In that latter instance, the remote monitoring station may interrogate the cooking 5 appliance for additional information and then make an independent judgment as to the necessity of repair.

It is contemplated that the present diagnostic system will monitor and accumulate the thermal characteristics of 10 the cooking appliance from cold start through its operation during the day until shut down. During that period, the diagnostic system can statistically determine - based on collected thermal data - the performance of the cooking appliance. Minor deviations may be recorded and stored in 15 memory or in a file to later provide a temperature profile history to assist a technician in serving the appliance, if a later failure occurs. If the deviation, however, is gross, it may display to the operator a message warning that the cooking appliance is unacceptable for cooking 20 purposes. If desired, the diagnostic system may be programmed in the latter case to disable the cooking appliance to eliminate any possible health risks.

In addition, acceptable values for the temperature 25 gradients for different cycles or modes of operation of the cooking appliance can be stored in the look-up table. For example, when the heating element is either pulsed at fixed or variable duty cycles the corresponding acceptable temperature gradients or profiles can be stored and then 30 compared with the measured gradients or profiles. As the cooking appliance ages, the acceptable values can also be updated so as to accommodate this change. This updating can be effected through the use of a portable computer that downloads to the system controller the acceptable values 35 for the thermal characteristics. Alternatively, the

-11-

diagnostic system can be programmed to learn or determine, for example, its own maximum or minimum values for the temperature gradient based on the past operating conditions of the cooking appliance. That is, the diagnostic system 5 learns what the normal range of values should be. Various programming techniques for effecting this latter methodology are well known in the art and may include the use of statistics, such weight averaging, standard deviation and the like, as well as artificial intelligence 10 or logic called "fuzzy-logic."

In results from experiment practice using 14" Pitco gas and electric fryers manufactured by Blodgett, Inc., the acceptable temperature gradient ranges were determined 15 empirically for the cooking appliance. Some exemplary values are tabulated below:

14" Pico Fryer $\Delta T = 250 - 300^{\circ}\text{F}$

20	Normal Time Range	Normal Gradient Range		
	<u>Δt (sec)</u>	<u>$\Delta T/\Delta t$ ($^{\circ}\text{F/sec}$)</u>		
	<u>Electric</u>	<u>Gas</u>	<u>Electric</u>	<u>Gas</u>
	91	116	0.55	0.43
	85	73	0.59	0.68
	101	110	0.50	0.45
25		112		0.45
		98		0.51
		97		0.52

From the above, the temperature gradient ranges were 30 0.50 - 0.59 ($^{\circ}\text{F/sec}$) and 0.43 - 0.68 ($^{\circ}\text{F/sec}$) for the electric and gas fryers, respectively. After additional data collection, however, it was empirically determined that the normal average temperature gradients were 0.53

-12-

(°F/sec) and 0.47 °(F/sec) for the electrical and gas fryers, respectively. Failures occurred at temperature gradients below 0.36 (°F/sec) and 0.35 °(F/sec) for the electric and gas fryers, respectively. As such, the 5 diagnostic system of the present invention indicated malfunctions in several fryers having a temperature gradient below these empirically determined minimum temperature gradients. Upon inspecting those fryers, they had either defective heating element(s) or improper line voltages to the heating element. Although it is typically 10 the case that the malfunction is associated with a temperature gradient that is too low, it should be understood that a temperature gradient that is too high will also be indicative of a malfunction.

15

In accordance with the principles of the invention, it is further contemplated that the diagnostic system of the present invention may alternatively monitor and accumulate the cooking profiles for either a single food product or a 20 plurality of food products. The term cooking profile has been employed in connection with cooking appliance controllers to denote the setting of various cooking parameter(s) during different portions of the cooking cycle, which parameters include temperature, pressure, 25 volumetric flow rate, humidity setting, and the like. See, for example, U.S. Patent No. 4,920,948, which is incorporated herein by reference.

For example, in cooking chicken, the cooking profile 30 may initially include a relatively high cooking temperature (T_H) for an amount of time, t_1 , and then a relatively low temperature (T_L) for an amount of time, t_2 , as illustrated in Fig. 4. Furthermore, it can be prepared under pressurized or non-pressurized cooking conditions. The 35 availability of a relatively large number of cooking

-13-

profiles is desirable because many establishments use the same cooking appliance to prepare the same food product in several different ways. Also, varying the amount of the particular food product that is to be cooked results in
5 different cooking profiles, for example, different cooking times.

Referring to Fig. 5, in this latter alternative embodiment of the present invention, the diagnostic system
10 further employs a display system 510, such as a CRT or LCD, to graphically display the cooking profile stored in memory for the particular food product that is being cooked. An illustrative display of a typical cooking profile 520 representative of the cooking temperature as a function of time is shown on display system 510. It should be clearly understood that in a likewise manner, the pressure,
15 humidity setting, and/or air flow rate, can also be displayed, if appropriate, either concurrently or at different times. This cooking profile represents a master cooking profile defined as the idealized cooking profile.
20

Such master cooking profiles provide a baseline for diagnosing between normal and faulty cooking conditions. As discussed more fully herein below, the master cooking profile is used specifically for comparison purposes with the current cooking profile defined as the profile received by the microprocessor during an actual cooking cycle. Importantly, monitoring the current cooking profile against the master cooking profile flags food products that are
25 improperly cooked or not cooked to the proper degree of doneness. Such monitoring and analysis substantially eliminates any possible health risks.
30

During normal operation, system controller 120 monitors and accumulates the actual or current cooking
35

-14-

profile of the food product that is being cooked. Thermal probe 115 provides temperature data to microprocessor 125, while probes 530, 540 and 550 provide pressure, air flow rate, and humidity data, respectively. More particularly,
5 each probe 115, 530, 540 and 550 collects data consisting of temperature, pressure, air flow rate and humidity, respectively, vis-a-vis A/D 145 as a function of time during a cooking cycle of the cooking appliance. Microprocessor 125 is connected to display system 510 for
10 graphically displaying the data collected by probes 115, 530, 540 and 550. Application specific software to effect such graphical displays may be readily realized by those skilled in the art and who have been equipped with understanding of the present invention as set forth herein.

15

Show in Fig. 6 are illustrative master and current cooking profiles superimposed for comparison purposes. The master cooking profile is stored in memory and any number of such master profiles may be stored so as to constitute
20 a library of master cooking profiles. By providing the ability to superimpose the master cooking profile over the current cooking profile, a nontechnically trained person can readily discern faulty cooking conditions and identify the cooking cycle as acceptable or good. Furthermore, it
25 also becomes more readily apparent to trained personnel where and to what extent the faulty cooking conditions are.

If desired, a cursor 555 may be provided on the display which may be positioned over any portion of the graphic display of the cooking profile. The specific values and of the cooking parameters corresponding to the location of cursor 555 may be displayed (master cooking profile, T=350°F; current cooking profile, T=339°F), thereby permitting the operator to readily compare cooking parameter values between the master and current cooking
35

-15-

profiles.

It is further contemplated that a cooking bar envelope 560 representing the lower and upper deviation limits from the master cooking profile can be alternatively superimposed with the current cooking profile, as shown in Fig 7. It should be clearly understood that the horizontal axis may alternatively be pressure, humidity setting, air flow rate, or any other cooking parameter appropriate for the particular appliance. In this manner, out-of-tolerance cooking conditions, indicated from deviations in the master cooking profile, are more readily discernable. Deviation limits can be established under which the quality of the cooked food product is deemed to be acceptable. Such deviation limits may be determined empirically and may be based on the type and model of the cooking appliance, among other things. Preferably, the deviation limits may be set through the use of statistics.

System controller 120 may be readily programmed to determine whether the current cooking profile is within cooking bar envelope 560, or to compare the current cooking profile against the master cooking profile. If the current cooking profile is outside preestablished limits of deviation or the cooking bar envelope, an appropriate signal - either audible or visual - can be displayed to the operator. Of course, current cooking profiles may be saved and stored in memory or on hard disk for later retrieval to assist a technician in serving the cooking appliance. If required, the cooking parameters may be automatically adjusted to match the current cooking profile to the master cooking profile using well known methods of feedback control, including the use of artificial intelligence or so-called "fuzzy-logic."

-16-

Alternatively, such current cooking profiles may be transmitted to a remote monitoring station where the faulty cooking conditions may be detected and identified using remote computers by comparing the current cooking profile 5 against the master. It is contemplated that the communication systems of U.S. Patent No. 4,812,963 and copending application serial no. 08/643,207, which are incorporated herein by reference, may be used to effect such transmission and the exchange of information necessary 10 to integrate various aspects of accounting, billing and servicing.

As yet another alternative, the current cooking profiles may be transmitted at the time of service to a 15 portable hand held terminal having a graphical display screen, such as a Palm/Laptop computer. Updated master cooking profiles may be stored in those hand held pocket terminals along with diagnostic software to detect and identify abnormal cooking conditions, which may affect the 20 quality of the food product. Preestablished deviation limits may be set to denote unacceptable food products. In this latter instance of using a palm/laptop computer, master and current cooking profiles are graphically displayed on the screen of the Palm/Laptop computer for 25 analysis by a trained technician. Such graphical displays may use menu driven software to assist in recalling, comparing and analysis the master and current cooking profiles for either a single food product or a plurality of food products.

30

It is understood that the embodiment herein is merely illustrative of the principles of the invention. Various modifications may be made by those skilled in the art which will embody the principles of the invention and fall within 35 the spirit and the scope thereof.

-17-

CLAIMS:

1. A method for monitoring the operation of a cooking apparatus comprising the steps of:
 - defining a master cooking profile for a particular food product representing the idealized cooking profile thereof for a particular cooking parameter;
 - storing said master cooking profile;
 - acquiring data for said particular cooking parameter as a function of time as the food product is being cooked,
 - said data representing a current cooking profile; and
 - graphically superimposing said master and current cooking profiles on a display for monitoring purposes.
2. The method of claim 1 wherein said cooking parameter is temperature.
3. The method of claim 1 wherein said cooking parameter is pressure.
4. The method of claim 1 wherein said cooking parameter is humidity setting.
5. The method of claim 1 wherein said cooking parameter is air flow rate.
- 25 6. The method of claim 1 further comprising the step of comparing said master and current cooking profiles, and identifying faulty cooking conditions based on said comparison.
- 30 7. The method of claim 1 further comprising the step of comparing said master and current cooking profiles, and identifying unacceptable cooked food product based on said comparison.

-18-

8. The method of claim 1 further comprising the step of comparing said master and current cooking profiles, and controlling the cooking operation of the cooking apparatus based on said comparison.

5

9. The method of claim 1 further including the step of downloading from a computer the master cooking profile.

10. The method of claim 1 further including the steps of transmitting the current cooking profile to a computer, and said computer graphically displaying said current cooking profile against a stored master cooking profile.

15. The method of claim 10 wherein said computer is a hand held terminal having a graphical display screen.

12. The method of claim 11 wherein said hand held terminal is a Palm/Laptop computer.

20. The method of claim 1 further including the steps of generating a cursor on said display along a portion of said master and current cooking profiles, and displaying the values of the cooking parameters corresponding to the location of the cursor on the master and current cooking profiles.

25. The method of claim 1 further including the step of determining whether said current cooking profile is within preestablished deviation limits from said master cooking profile.

30. The method of claim 14 further including the step of graphically displaying said preestablished deviation limits as a cooking bar envelope on said display.

-19-

16. A method for monitoring the operation of a cooking apparatus comprising the steps of:

acquiring a master cooking profile for a particular food product representing the idealized cooking profile thereof for a particular cooking parameter;

5 acquiring data for said particular cooking parameter as a function of time so as to constitute a current cooking profile; and

10 comparing said master and current cooking profiles to determine whether the food product was cooked under acceptable cooking conditions.

15 17. The method of claim 16 further including the step of graphically superimposing and displaying the master and current cooking profiles.

20 18. The method of claim 16 further including the step of determining whether said current cooking profile is within preestablished deviation limits from said master cooking profile.

25 19. The method of claim 18 further including the step of graphically displaying said preestablished deviation limits as a cooking bar envelope together with said current cooking profile.

20. The method of claim 16 wherein said cooking parameter is temperature.

30 21. The method of claim 16 wherein said cooking parameter is pressure.

22. The method of claim 16 wherein said cooking parameter is humidity setting.

-20-

23. The method of claim 16 wherein said cooking parameter is air flow rate.

5 24. The method of claim 16 further comprising the step of controlling the cooking operation of the cooking apparatus based on the comparison of said master and current cooking profiles.

10 25. The method of claim 16 further including the step of downloading from a computer the master cooking profile.

15 26. The method of claim 16 further including the steps of transmitting the current cooking profile to a computer, and said computer graphically displaying said current cooking profile against a stored master cooking profile.

20 27. The method of claim 16 further including the steps of transmitting the current cooking profile to a computer, and said computer graphically displaying said current cooking profile with a cooking bar envelope representing preestablished deviation limits from said master cooking profile.

25 28. The method of claim 27 wherein said computer is a hand held terminal having a graphical display screen.

30 29. The method of claim 27 wherein said hand held terminal is a Palm/Laptop computer.

35 30. An apparatus for monitoring the operation of a cooking apparatus comprising:
 means for acquiring a master cooking profile for a particular food product representing the idealized cooking profile thereof for a particular cooking parameter;

-21-

memory for storing said master cooking profile;
means for acquiring data for said particular cooking
parameter as a function of time as the food product is
being cooked, said data representing a current cooking
5 profile; and

display means for graphically superimposing said
master and current cooking profiles for monitoring
purposes.

10 31. The apparatus of claim 30 wherein said means for
acquiring includes a temperature sensor.

32. The apparatus of claim 30 wherein said means for
acquiring includes a pressure sensor.

15 33. The apparatus of claim 30 wherein said means for
acquiring includes an air flow rate sensor.

20 34. The apparatus of claim 30 wherein said means for
acquiring includes a humidity sensor.

25 35. The apparatus of claim 30 further comprising
means for comparing said master and current cooking
profiles so as to identify faulty cooking conditions based
on said comparison.

30 36. The apparatus of claim 30 further comprising
means for comparing said master and current cooking
profiles so as to identify unacceptable cooked food product
based on said comparison.

37. The apparatus of claim 30 wherein said master
cooking profile is downloaded from a computer.

35 38. The apparatus of claim 37 wherein said computer

-22-

is a hand held terminal having a graphical display screen.

39. The apparatus of claim 38 wherein said hand held terminal is a Palm/Laptop computer for graphically displaying said current cooking profile against a stored master cooking profile.
5

40. The apparatus of claim 30 further including means for graphically displaying preestablished deviation limits from said master cooking profile along with said current cooking profile.
10

41. The apparatus of claim 40 wherein said deviation limits are in the form of a cooking bar envelope.

(54) Title: DIAGNOSTIC SYSTEM FOR MONITORING COOKING PROFILES

(57) Abstract

The diagnostic system of the present invention monitors and accumulates thermal signatures or characteristics during at least one operational mode of a cooking appliance (105). These thermal signatures or characteristics are collected through the same temperature sensor (115) used to regulate the temperature of the cooking appliance and then stored in, for example, a look-up table (130). Advantageously, this may be accomplished without the need for special sensors or interface boards. The thermal signatures or characteristics may include first order or higher order temperature gradients, as well as temperature profiles. The stored thermal signatures provide a baseline from which the diagnostic system can detect and identify whether the cooking appliance is working under normal operating conditions. In an alternative embodiment, the diagnostic system monitors and accumulates the cooking profiles for either a single food product or a plurality of food products. The current cooking profile is graphically displayed and compared against the master cooking profile (520) to flag food products that are improperly cooked or not cooked to the proper degree of doneness. Such monitoring and analysis substantially eliminates any possible health risks. Also, such master cooking profiles also provide a baseline for diagnosing between normal and faulty cooking conditions.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US98/18317

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) : G01K 1/08

US CL : 374/149

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 374/45, 102, 104, 107, 112, 149; 99/324, 337, DIG. 10; 219/ 490, 492, 494, 497, 499, 501, 506, 507, 508; 364/557

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS in above US classes/subclasses (cook?, temperature, monitor, compare)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	US 5,043,860 (Koether et al.) 27 August 1991 (27/08/91), col. 2, lines 53-68, col. 3, lines 1-49, col. 4, lines 3-12), col. 5, lines 1-20.	1-41
Y	US 4,920,948 (Koether et al.) 01 May 1990 (01/05/90), abstract, cols. 1-2.	2-5, 8, 20-24, and 31-34

 Further documents are listed in the continuation of Box C.

See patent family annex.

• Special categories of cited documents:	"T"	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
• A: document defining the general state of the art which is not considered to be of particular relevance	"X"	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
• E: earlier document published on or after the international filing date	"Y"	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
• L: document which may throw doubt on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"&"	document member of the same patent family
• O: document referring to an oral disclosure, use, exhibition or other means		
• P: document published prior to the international filing date but later than the priority date claimed		

Date of the actual completion of the international search
